TECHNOLOGIES FOR FORMING SOCIAL MOTIVATION IN PRESCHOOL CHILDREN

Gafurdjanova Malokhat Akramjon kizi
Kimyo international university in
Tashkent Namangan branch

Abstract

This article examines contemporary technologies and methodological approaches for developing social motivation in preschool-aged children. Social motivation, defined as the intrinsic drive to engage with others, understand social cues, and participate in collective activities, serves as a fundamental component of child development and school readiness. The research analyzes the theoretical foundations of social motivation formation, explores age-specific characteristics of preschoolers that influence motivational development, and presents evidence-based pedagogical technologies for fostering prosocial behaviors, cooperative skills, and interpersonal competencies. Through systematic analysis of both traditional and innovative approaches including play-based learning, project methods, storytelling techniques, digital technologies, and socio-dramatic activities, this study demonstrates that intentional implementation of structured motivational technologies significantly enhances children's social-emotional development, peer relationships, and readiness for formal education. The article provides practical recommendations for educators, psychologists, and parents working with preschool children in various educational settings.

Key words: social motivation, preschool children, pedagogical technologies, socialization, emotional development, early childhood education, prosocial behavior, cooperative learning

Introduction

The preschool period, spanning ages three to seven, represents a critical developmental window during which children establish foundational social competencies that influence their lifelong interpersonal functioning, academic success, and psychological well-being. Social motivation—the inherent desire to connect with others, understand social norms, and engage in collective activities—emerges as a central construct determining how effectively children navigate their expanding social worlds (Tomasello, 2019).

Contemporary research in developmental psychology, pedagogy, and neuroscience increasingly emphasizes that social motivation is not merely an innate trait but a complex competency that can be systematically cultivated through intentional educational practices. Unlike earlier perspectives viewing social development as largely maturational, current understanding recognizes the profound influence of environmental factors, pedagogical interventions, and structured learning experiences in shaping children's social motivational patterns (Wentzel & Miele, 2016).

The formation of social motivation during the preschool years holds particular significance for several reasons. First, this period coincides with dramatic expansion in children's social networks as they transition from primarily family-based interactions to peer-dominated environments in educational settings. Second, preschool children develop increasingly sophisticated theory of mind capabilities, enabling them to understand others' perspectives, intentions, and emotional states—cognitive foundations essential for socially motivated behavior (Wellman, 2014). Third, habits and attitudes established during early

childhood tend to persist, making preschool an optimal intervention point for fostering positive social orientations.

Despite widespread recognition of social motivation's importance, significant questions remain regarding optimal approaches for cultivating these competencies. What specific technologies prove most effective for developing social motivation in preschool children? How do different pedagogical approaches address the unique developmental characteristics of this age group? What role do contemporary digital technologies play in supplementing traditional socialization methods? How can educators systematically assess and support individual differences in social motivational development?

This article addresses these questions through comprehensive analysis of technologies for forming social motivation in preschool children. The term "technology" is employed here in its pedagogical sense, referring to systematic, replicable methodologies and structured approaches rather than exclusively digital tools. The research synthesizes theoretical frameworks, empirical evidence, and practical applications to provide educators with evidence-based guidance for fostering social motivation in early childhood settings.

Theoretical Foundations of Social Motivation Development

Understanding the technologies for developing social motivation requires grounding in relevant theoretical perspectives that explain how and why children become socially motivated.

Social Learning Theory

Bandura's (1977) social learning theory posits that children acquire social behaviors and motivations through observation, imitation, and modeling. Preschool children are particularly attentive to adult and peer models, reproducing observed behaviors when they perceive positive consequences. This theoretical framework suggests that teachers and parents must consciously model prosocial behaviors, cooperative interactions, and empathetic responses, as children will internalize these observed patterns. Technologies based on social learning principles include structured role-modeling activities, peer tutoring programs, and observation-based learning experiences.

Sociocultural Theory

Vygotsky's (1978) sociocultural perspective emphasizes that cognitive and motivational development occur through social interaction within culturally defined contexts. The concept of the Zone of Proximal Development highlights how children advance through collaborative activities with more competent partners. Social motivation develops as children engage in joint activities requiring coordination, communication, and mutual adjustment. This theory undergirds technologies emphasizing collaborative projects, guided participation, and scaffolded social experiences where children progressively assume greater responsibility for social coordination.

Attachment Theory

Bowlby (1969) and Ainsworth's attachment research demonstrates that children's early relational experiences with caregivers create internal working models influencing subsequent social motivation. Securely attached children demonstrate greater confidence in social exploration, more positive peer relationships, and stronger prosocial orientations. Pedagogical technologies informed by attachment theory prioritize creating secure, responsive educational environments where children feel emotionally safe to engage socially.

Self-Determination Theory

Deci and Ryan's (2000) self-determination theory identifies three fundamental psychological needs—autonomy, competence, and relatedness—that when satisfied, promote intrinsic motivation including social engagement. For preschool children, technologies

supporting autonomy (meaningful choices in social activities), competence (achievable social challenges with positive feedback), and relatedness (genuine connections with peers and adults) foster authentic social motivation rather than mere compliance.

Theory of Mind Development

Research on theory of mind—the ability to attribute mental states to oneself and others—reveals that preschool years witness dramatic advances in perspective-taking, emotion recognition, and understanding of social causality (Wellman, 2014). These cognitive developments enable increasingly sophisticated social motivation. Technologies effective during this period leverage children's emerging theory of mind capabilities through activities requiring perspective coordination, emotion identification, and social problem-solving.

Developmental Characteristics Influencing Social Motivation

Preschool children exhibit distinctive characteristics that both facilitate and constrain social motivational development, necessitating age-appropriate technological approaches.

Egocentrism and Emerging Perspective-Taking

Young preschoolers (ages 3-4) demonstrate egocentric thinking, struggling to recognize that others hold different perspectives. By age 5-6, most children develop basic perspective-taking abilities. Technologies must accommodate this developmental progression, initially using concrete, explicit guidance about others' feelings and gradually introducing activities requiring independent perspective coordination.

Play as Primary Learning Mode

For preschool children, play represents the leading activity through which development occurs (Vygotsky, 1978). Social motivation technologies prove most effective when embedded within playful contexts. Children demonstrate greater social engagement, cooperation, and prosocial behavior during play activities compared to direct instruction.

Emotional Regulation Capacities

Preschoolers are developing emotional self-regulation abilities essential for successful social interaction. Technologies supporting social motivation must simultaneously address emotional competencies, teaching children to recognize, label, and manage emotions arising in social contexts.

Concrete Operational Thinking

Preschool children think concretely, requiring tangible, observable examples rather than abstract social concepts. Technologies emphasizing experiential learning, visual supports, and concrete social scenarios prove more effective than abstract discussions of social principles.

Attention and Impulse Control

Young children's limited attention spans and developing impulse control influence their capacity for sustained social interaction. Technologies must structure social activities in brief, engaging segments with clear routines and expectations.

Language Development

Rapid language acquisition during preschool years profoundly impacts social motivation. Expanding vocabulary for emotions, social situations, and interpersonal concepts enables children to navigate social interactions more effectively. Technologies integrating language development with social learning prove particularly powerful.
